Manual QA Testing Assessment

1. What exactly should search match: product name only, or also description, brand, SKU, category, and color?

Priority / Rationale: Critical: We need to know which fields are searchable so that the search results meet the client's expectations.

QA Feedback / Proposed Assumption: I recommend searching across product names and other relevant product details. For the DemoQA adaptation, I would focus on book titles and the metadata actually available on the page.

2. Should search run dynamically while typing, or only after pressing Enter or clicking a Search button?

Priority / Rationale: Critical: This defines how users interact with the search feature and when results should update.

QA Feedback / Proposed Assumption: I recommend dynamic search while typing. For DemoQA, I would first verify the available search behavior and test it without assuming that a separate search API exists.

3. Should matching be case-insensitive?

Priority / Rationale: High: Users should get consistent results regardless of whether they use uppercase or lowercase letters.

QA Feedback / Proposed Assumption: I recommend case-insensitive matching. For example, searching for "stainless steel thermos" should return the same relevant results as "Stainless Steel Thermos".

4. Should partial words and multiple keywords match? For example, "stain steel" or "thermos steel".

Priority / Rationale: High: This determines how the search handles incomplete words and multiple keywords.

QA Feedback / Proposed Assumption: I recommend supporting partial-word and multiple-keyword searches. The client should clarify whether all keywords or any matching keyword are required. I would test the behavior using available book titles and metadata in DemoQA.

5. How should leading or trailing spaces, repeated spaces, punctuation, and special characters be handled?

Priority / Rationale: High: Improper handling of these inputs may lead to unexpected results or search failures.

QA Feedback / Proposed Assumption: I recommend trimming leading and trailing spaces and handling repeated spaces consistently. I would also test punctuation and special characters to check whether the search returns appropriate results without errors.

6. What should happen when no items match the search query?

Priority / Rationale: High: Users need clear feedback when their search does not return any results.

QA Feedback / Proposed Assumption: I recommend displaying a clear "No results found" message and ensuring that unrelated or previous results are not displayed.

7. What should happen when the search field is empty or the user clears the query?

Priority / Rationale: High: The expected behavior should be clear when users start a search or reset it.

QA Feedback / Proposed Assumption: I recommend displaying the default list when the search field is empty and restoring the full list when the user clears the query, unless the client specifies otherwise.

8. Are there minimum or maximum query lengths, and how should very long inputs be handled?

Priority / Rationale: Medium: Input-length limits help prevent usability issues and unexpected behavior with unusually long queries.

QA Feedback / Proposed Assumption: I recommend defining a reasonable maximum input length. I would test empty input, a single character, a normal query, and a very long string to check validation and application stability.

9. What are the expected performance and accessibility requirements, such as response time, keyboard navigation, and screen-reader support?

Priority / Rationale: Medium: Search should respond within an acceptable time and remain accessible to different users.

QA Feedback / Proposed Assumption: I recommend defining a measurable response-time target and supporting keyboard interaction. I would also check whether the search field has an appropriate accessible label and whether users can operate it without a mouse.

10. Should search results preserve pagination and sorting, and what should the expected API response contain?

Priority / Rationale: Medium: These details help maintain consistent results when the product list is large and when the UI communicates with a backend.

QA Feedback / Proposed Assumption: I recommend clarifying how pagination and sorting should work after a search. If a search API is available, I would also verify that its response matches the results displayed in the UI.
